

X86 SYMBOLS v1

Symbols can be

- * Undefined - we've referenced the symbol but don't know what it is yet. We assume 16 bit address for now (offset from unknown seg)

If defined, they can be:

- * Integer constant
- * String constant
- * Address offset from a segment
 - which could be fixed addresses ②
 - ① - or relocatable address in this or another
 - ① - or external address
- * Unusable. Because we have done something like "ORG() >> 2" in a relocatable segment.

- ① These need to go into the fixup table
- ② Would be in same or different seg in the same module
